## Abstract

### Background:

The current study was designed to determine antibiotic resistance profile, detection of antimicrobial resistance and virulence-related genes among enterococcus species.

### Methods:

Altogether, one hundred fifty *enterococcal* isolates were collected from various clinical specimens and identified by Polymerase chain reaction (PCR). Antibiotic susceptibility testing and MICs of vancomycin were carried out as per CLSI guidelines. A series of PCR reactions were used to screen vancomycin-resistant genes (*vanA*, *vanB*, and *vanD*) and virulence-related genes (*esp*, *ace*, *asa1*, *geIE* & *cylA*) among VRE *enterococcus* species.

### Results:

The isolated enterococcal strains comprised 62.6% *E. faecalis*, 33.4% *E. faecium*, and 4% of other species. Overall *enterococcus* showed a high level of resistance; 94% to erythromycin, followed by ciprofloxacin 82.6%, levofloxacin 70%, and vancomycin 16%. The 57.4% of the isolates were recovered from hospitalized patients and 96% of the *enterococcus* isolates were multi-drug resistant. The MICs of vancomycin-resistant strains remained in the range of 32 ug/ml to 256 ug/ml for the majority of the isolates. The vancomycin-resistant phenotypes *vanA*, *vanB*, and *vanD* were found in 29.2%, 37.5%, and 33.3% isolates respectively. Regarding virulence determinants the observed percentages were as follows; *esp*: 16.6%, *asa1*: 70.8%, *geIE*: 25%, *ace*: 33.3%, and *cylA*: 25%.

### Conclusion:

The majority of the isolates were *E. faecalis* and multi-drug resistant. The VRE isolates carried antimicrobial resistance and virulence-related genes, and *vanA,B,D* phenotypes were the most common among VRE isolates.

**Key words:** Antimicrobial resistance, Enterococcus, Minimum inhibitory concentration, Vancomycin resistant enterococci, Virulence factors, Antimicrobial resistance gene

## Резюме.

### История вопроса:

Настоящее исследование было разработано для определения у разных видов энтерококков профиля устойчивости к антибиотикам, выявления устойчивости к противомикробным препаратам и генов, связанных с вирулентностью.

### Методы:

Всего были собраны сто пятьдесят изолятов энтерококков из различных клинических образцов, идентифицированных с помощью полимеразной цепной реакции (ПЦР). Тестирование чувствительности к антибиотикам и определение минимальной ингибирующей концентрации (МИК) ванкомицина проводились в соответствии с рекомендациями Института клинических и лабораторных стандартов (CLSI). Серия реакций ПЦР использовалась для скрининга генов устойчивости к ванкомицину (*vanA*, *vanB* и *vanD*) и генов вирулентности (*esp*, *ace*, *asa1*, *gelE* и *cylA*) среди видов ванкомицинрезистентных энтерококков (ВРЭ).

### Результаты:

Выделенные штаммы энтерококков включали 62,6% *E. faecalis*, 33,4% *E. faecium* и 4% других видов. В целом энтерококки показали высокий уровень устойчивости: 94% - к эритромицину, за которым следуют ципрофлоксацин (82,6%), левофлоксацин (70%) и ванкомицин (16%). 57,4% изолятов были получены от госпитализированных пациентов, и 96% изолятов энтерококков были с множественной лекарственной устойчивостью. МИК для ВРЭ штаммов большинства изолятов варьировали в диапазоне от 32 мкг/мл до 256 мкг/мл. ВРЭ фенотипы в виде *vanA*, *vanB* и *vanD* были обнаружены у 29,2%, 37,5% и 33,3% изолятов соответственно. В отношении факторов вирулентности, получены следующие распределения: *esp* – 16,6%, *asa1* – 70,8%, *gelE* – 25%, *ace* – 33,3% и *cylA* – 25%.

### Заключение:

Большинство изолятов были *E. faecalis* и имели множественную лекарственную устойчивость. ВРЭ изоляты несли гены устойчивости к противомикробным препаратам и гены, связанные с вирулентностью, а фенотипы *vanA*, *B*, *D* были наиболее распространены среди ВРЭ изолятов.

**Ключевые слова:** устойчивость к противомикробным препаратам, энтерококки, минимальная ингибирующая концентрация, ванкомицинрезистентные энтерококки, факторы вирулентности, ген устойчивости к противомикробным препаратам

## 1 Introduction

2 Enterococci persistently emerged as important nosocomial pathogens globally and  
3 cause a wide range of infections such as bacteremia, meningitis, urinary tract  
4 infections, intra-abdominal and soft tissue infections, etc (1). The majority of the  
5 clinical enterococcal infections are caused by two species; *Enterococcus*  
6 *faecalis* and *Enterococcus faecium* (2). Due to the frequent use of antibiotics in  
7 clinical practices, the emergence and spread of multi-drug-resistant enterococci such  
8 as vancomycin-resistant enterococci (VRE) has been observed (1). Globally, this  
9 rapid emergence of VRE strains is considered a major public health concern. Besides  
10 increased morbidity and mortality of VRE infections, increased length of  
11 hospitalization and financial burden have also been reported (3).

12 The resistance to vancomycin in enterococci is mainly mediated by *van* gene  
13 phenotypes such as *vanA*, *vanB*, *vanC*, *vanD*, and *vanE* genes, etc. The *vanA*  
14 and *vanB* have the highest clinical importance in *enterococci* among vancomycin-  
15 resistant phenotypes (4). The spread of multi-drug-resistant *enterococci* strains and  
16 resistance-related genes has serious health implications. Furthermore, treatment  
17 options for VRE infections are quite limited including linezolid, teicoplanin, and  
18 fosfomicin (3). Moreover, various virulence determinants associated with  
19 pathogenesis such as aggregation substance (*Asa1*), *enterococcal* surface protein  
20 (*Esp*), cytolysin (*CylA*), collagen binding protein (*ace*), and gelatinase (*gelE*) are  
21 important for the progress of infection among these strains (5).

22 In Pakistan, the VRE is posing a challenge for clinicians as well as for hospital  
23 infection control practitioners. Despite its increased prevalence, data are scarce  
24 regarding its detailed characterization from Pakistan. The aim of the current study  
25 was to evaluate the frequency of enterococcal infections, antibiotic resistance  
26 profile, detection of antimicrobial resistance and virulence-related genes in clinical  
27 strains of enterococcus isolated from tertiary care hospital in the northwest of  
28 Pakistan.

## 29 **Materials and methods**

### 30 **Bacterial isolates**

31 A total of one hundred and fifty (n=150) non-repetitive *enterococcal* isolates were  
32 collected from various clinical specimens of patients admitted at a tertiary care  
33 teaching Hospital in Peshawar, Pakistan from January 2020 to February 2021. The  
34 isolates were re-identified at the Department of Medical Lab Technology, The  
35 University of Haripur by routine microbiological techniques (6). The Polymerase  
36 chain reaction (PCR) was performed using specific primers *ddl E.faecium* and *ddl E.*  
37 *faecalis* to confirm the identity of *E. faecium* and *E. faecalis* as described elsewhere  
38 (7). Ethical approval was obtained from the departmental ethical committee at the  
39 University of Haripur.

### 40 **Antimicrobial susceptibility testing**

41 Antimicrobial susceptibility was carried out using the Kirby Bauer disc diffusion  
42 method according to the guidelines of the Clinical Laboratory Standard Institute  
43 (CLSI,2020) (8). The antibiotic discs were obtained from (Oxide, England). The  
44 antibiotic discs and concentrations used were as follows; Vancomycin (30 µg),  
45 Linezolid (30 µg), Teicoplanin (30 µg), Gentamicin (10 µg), Penicillin (10 µg),  
46 Amoxicillin (10 µg), Doxycycline (30 µg), Minocycline (30 µg), Ciprofloxacin (30  
47 µg), Levofloxacin (30 µg), Norfloxacin (30 µg), Erythromycin (15 µg),  
48 Fosfomycine (50 µg), Chloramphenicol (30 µg), Nitrofurantoin (300 µg),  
49 Rifampicin (5 µg) and Ampicillin (10 µg). The interpretation of the zone of  
50 inhibition was performed as per CLSI guidelines (8).

### 51 **Determination of Vancomycin Minimum inhibitory concentrations (MICs)**

52 The enterococcal isolates resistant to vancomycin by disc diffusion method were  
53 further tested for minimum inhibitory concentrations. The MICs of vancomycin  
54 were determined by E.test using commercially available strips  
55 (MTS,Liofilchem,Italy). The interpretation of vancomycin MICs was carried out

56 according to CLSI guidelines. The reference strains *E. faecium*, (ATCC 19434)  
57 and *E. faecalis*, (ATCC 19433) were used as control strains (8).

### 58 **Detection of antimicrobial resistance and virulence related genes:**

59 Enterococcal genomic DNA was extracted from overnight culture by boiling method  
60 (9). The vancomycin resistance associated genes *vanA*, *vanB*, and *vanD* and  
61 virulence related genes (*esp*, *ace*, *asa1*, *gelE*, and *cylA*)  
62 among *E. faecium* and *E. faecalis* were detected by using a series of PCR reactions  
63 as described earlier (10, 11).

### 64 **Statistical analysis:**

65 The descriptive variables were expressed in percentages and frequencies. A Pearson  
66 test was used for correlation among the variables. The statistical analysis was done  
67 by SPSS (version 22) and a *p*-value of <0.05 was considered statistically  
68 significant. Individual antibiotics sensitivity vs resistance percentages were cross tabulated  
69 among *E. faecalis* and *E. faecium* and the Odds ratio (OR) were determined.

### 70 **Results:**

#### 71 **Characteristics of the study participant:**

72 During the study period, 62.6% (n=94) *E. faecalis*, 33.4% (n=50) *E. faecium*, and  
73 4% (n=6) of other species were isolated. The distribution of the isolated strains from  
74 different specimens is shown in Table:1. The patient population of the isolated  
75 strains was 42.6% (n=64) community-acquired whereas 57.4% (n=86) were  
76 hospitalized. The majority, 56% (n=84/150) of the isolates were recovered from  
77 patients who were >50 years old and 58% (n=49/84) of them were inpatients.  
78 Interestingly 6% (n=9/150) of the total isolates were recovered from children (< 1  
79 year) and 66.6% (n=6/9) of them were inpatients.

#### 80 **Antimicrobial susceptibility**

81 Antibiotic susceptibility was carried out and the predominant isolated strain *E.*  
82 *faecalis* showed the highest level of resistance, 95.7% (n=90/94) to erythromycin,  
83 followed by ciprofloxacin 84% (n=79/94), amoxicillin 66% (n=62/94) and

84 vancomycin 17%(n=16/94). Low percentages of resistance were observed against  
85 linezolid as shown in Table: 2. Among *E. faecium* isolates the resistance against  
86 erythromycin was 90% (n=45/50), followed by ciprofloxacin and gentamicin 80%  
87 (n=40/50 each), levofloxacin 76% (38/50), vancomycin and linezolid 16% (n=8/50)  
88 and 4% (n=2/50) respectively. Other species of enterococcus (other than *E.*  
89 *faecium* & *E. faecalis*) were resistant to erythromycin 100% (n=6/6), followed by  
90 ciprofloxacin and gentamicin 83.3%(n=5/6) each. No resistance was observed  
91 among other species against vancomycin and linezolid as shown in Table: 02.

### 92 **Vancomycin Minimum Inhibitory Concentrations:**

93 Sixteen percent (n=24) of the isolates (*E. faecium* and *E. faecalis*) were  
94 vancomycin-resistant. Whereas no vancomycin resistance was observed against  
95 other enterococcus species. The MIC values for vancomycin against *E.*  
96 *faecium* and *E. faecalis* remained higher and fell in the range of 32 ug/ml to 256  
97 ug/ml as shown in Supplementary Table 1. Overall, the difference in vancomycin  
98 MIC values among *E. faecium* and *E. faecalis* was statistically not significant  
99 ( $p=0.624$ ). The mean distribution of MICs of *E. faecium* and *E. faecalis* is shown in  
100 Figure 1.

101

### 102 **Vancomycin-resistant phenotypes and virulence determinants:**

103 The percentages of vancomycin-resistant phenotypes among *E. faecium* vs *E.*  
104 *faecalis* were as follows: *vanA*; 50% (n=4) vs 19% (n=3), *vanB*; 12.5% (n=1) vs  
105 62.5% (n=10) and *vanD*; 75% (n=6) vs not detected. Overall MICs for *vanA*,*vanB*,  
106 and *vanD* positive isolates remained above 16 ug/ml (Supplementary Table 1).

107 A total of five different virulence factors were scrutinized among twenty-four VRE  
108 isolates. The prevalence of the virulence factors among *E. faecium* and *E. faecalis*  
109 is shown in table:3. Overall no significant differences have been observed  
110 between *E. faecium* and *E. faecalis* virulence genes prevalence.

### 111 **Multi-drug resistant Enterococci:**

112 The highest percentage, 96% (n=144/150) of the *enterococcus* isolates had multi-  
113 drug resistant patterns. Overall, 94.4% (n=136/144) of the isolates were resistant  
114 to >5 tested antibiotics and 26.3% (n=38/144) were resistant to >10 tested antibiotics  
115 and mainly were penicillin, cephalosporin, monobactam, quinolone and  
116 aminoglycosides as shown in Supplementary Table 1.

## 117 **Discussion**

118 The current study was carried out to investigate the growing importance of multi-  
119 drug-resistant enterococcal infections in a tertiary care hospital in Khyber  
120 Pakhtunkhwa (KP), Peshawar, Pakistan. The available collected clinical information  
121 confirmed the established risk factors for the acquisition of various enterococcal  
122 infections such as hospitalization, advanced age, and neonates which are parallel to  
123 the other reports (12, 13). In our study majority of the enterococcal infections were  
124 observed in the ages above 50 years which is similar to the other reported studies  
125 (12, 13). In the current study, the predominant species is *E. faecalis*. The same  
126 pattern has been observed among clinical isolates from other studies (11, 14). It has  
127 been reported that majority of the enterococcal infections are caused by *E.*  
128 *faecalis* as compared to other enterococcal species. Furthermore, it has been  
129 reported that *E. faecalis* carries more virulence factors in comparison to other  
130 Enterococcal species; resulting in its higher pathogenicity (10).

131 Over the time, the bacteria acquired resistance to anti-enterococcal antibiotics such  
132 as glycopeptides, ampicillin, and aminoglycosides. This might contribute to the  
133 increased prevalence of *E. faecalis* infections. However, recently certain studies  
134 have reported a relative shift in favor of *E. faecium* (2, 12, 15). In our study high  
135 level of resistance to *E. faecalis* has been observed against erythromycin,  
136 ciprofloxacin, gentamicin, and ampicillin which is in accordance with the previous  
137 studies (16, 17). The high level of resistance to enterococcal strains against  
138 gentamicin is a major concern as this might limit the option of combination therapy  
139 (Cell wall inhibitor antibiotics like ampicillin or vancomycin plus aminoglycosides

140 such as gentamicin) which could be considered essential for the treatment of severe  
141 infections. Linezolid which was available for the first time in the year 2000 has been  
142 considered an alternate drug of choice for treating VRE infection. This is active  
143 against both *E. faecalis* and *E. faecium* (16). In our study, the resistance of linezolid  
144 against *E. faecium* and *E. faecalis* was 4% and 3.1% respectively.

145 Surprisingly, in the current study, 96% of the enterococcus isolates were multi-drug  
146 resistant which is parallel with the previous report from Iran (18). In our country,  
147 the treatment for the infections associated with MDR enterococci is complicated due  
148 to extensive misuse of antibiotics. Furthermore, the acquisition of antimicrobial  
149 resistance and its dissemination through plasmid and conjugative transposons play  
150 an important role in the progression of MDR enterococci (18).

151 The prevalence of VRE in the current study was 16% which is slightly raised from  
152 the results reported from Germany, Iran, and Italy; 11.2%, 9.4%, and 9%  
153 respectively(19). However, the prevalence of VRE varies in different regions and a  
154 high frequency of VRE has been reported in the UK: (14.5%), Saudi Arabia :  
155 (17.3%), and Turkey: (80.2%) (14, 20, 21). The MICs of vancomycin in the majority  
156 cases for both *E. faecium* and *E. faecalis* fell in the range of 32 ug/ml to 256 ug/ml.  
157 The emergence of VRE in enterococci is considered one of the influential factor of  
158 enterococcal nosocomial infections (10). The increased prevalence of VRE in  
159 Pakistan is a serious concern, especially for the treatment of multi-drug resistant  
160 Gram-positive infections.

161 In the current study, we observed various percentages of *vanA*, *vanB*, and *vanD*  
162 phenotypes among VRE isolates. A study conducted in Iran reported that all VRE  
163 isolates were *vanA* phenotype (22). One possible explanation for this variation  
164 might be the presence of other resistance genes such as *vanB* and *vanD* in the current  
165 study and the presence of other resistance mechanisms including thick cell wall  
166 production etc. However, some studies have reported variations in *van* phenotypes  
167 which are following our findings (2, 19, 23).

168 The observed prevalence of *the ace* gene among *E. faecalis* and *E. faecium* were  
169 44% and 12.5% respectively. In other studies, the reported prevalence of *ace* was  
170 42% and 39% respectively (11, 24). Previously, it was hypothesized that *ace* gene  
171 products facilitate bacterial binding to the root dentin canal. Furthermore, they found  
172 out a significant correlation between the intact gene presence and subsequent  
173 attachment to dentin by *E. faecalis* (25). Thus the presence of *the ace* gene in  
174 enterococcus species might be considered as an important virulence factor (11, 25).  
175 Moreover, the frequency of *gelE* gene (25%) almost remained the same in both  
176 species. Gelatinase is a zinc metalloprotease with hydrolytic ability (16). The  
177 observed frequency is slightly higher from the previous report which was 16% (26).  
178 The percentages of *cylA*, *asa1*, and *esp* genes among *E. faecalis* and *E.*  
179 *faecium* were 12.5% vs 25%, 94% vs 25%, and 6% vs 37.5% respectively.  
180 Previously no *cylA* gene was detected in any isolates of *E. faecium* and low  
181 prevalence of *asa1*(2%) and *esp* (17.5%) were reported (2, 27) . Other studies  
182 reported a high frequency of *esp* gene among clinical isolates of vancomycin  
183 resistant *E. faecium* in comparison to fecal isolates. This increased prevalence of *the*  
184 *esp* gene in clinical isolates might indicate its role in enterococcal pathogenesis (2,  
185 28). The *asa1* gene-encoded aggregation substances facilitate binding to the host  
186 epithelium and during conjugation mediate bacterial aggregation and participate in  
187 plasmid exchange (16).

188 Conclusively, our study reported that *E. faecalis* was most prevalent among  
189 other *enterococcus* species. The majority of the isolates were multi-drug resistant  
190 and the highest percentages of resistance were observed against erythromycin,  
191 ampicillin, aminoglycosides, and vancomycin. The VRE isolates carried  
192 antimicrobial resistance and virulence-related genes and the most common  
193 glycopeptides-resistant phenotypes were *vanA,B,D* among VRE enterococcus  
194 isolates. Furthermore, due to this increased prevalence of MDR enterococci in

195 clinical isolates, appropriate control measures and surveillance are essential to  
196 control the transmission and emergence of these isolates in hospitals.

197

### 198 **Author Contributions**

199 This study was designed and supervised by Ihsan Ali and Abdul Jabbar. Jamshid  
200 Ullah, Atif aziz, Inam Ullah, Muhammad Umair, Aman ullah and Hanif Ullah  
201 carried out bench work and assembled the data. Matiullah, Mutiullah, Abdul Jabbar  
202 and Ihsan Ali performed analysis, interpretation and drafted the manuscript. The  
203 final manuscript were read and approved by all authors.
